### ABSTRACT

*This study is part of a goal to investigate chemical composition, antibacterial, antifungal and antioxidant activities of the flower buds extracts from the Algerian Populus nigra L., which were collected from Djarifet - mansourah at Tlemcen city in the West Northern of Algeria.*

*In organic extracts, tanins, flavonoïds, coumarins, alkaloids and terpenoïds were the principals secondary metabolites identified from the flower buds of black poplar. Antibacterial and antifungal activities of extracts were tested using agar-well diffusion method and micro-well determination of MIC assay against eleven bacteria and two Candida species. It was found that extracts of black poplar buds exhibit antibacterial and anticandidal activities with agar disk diffusion (7 to 43mm) and MIC methods (MIC= 90.33 µg/ml against several strains of bacteria and MIC=45.16 µg/ml against Candida albicans). The antioxidant effect of hydroalcoholic extract was evaluated using DPPH and FRAP assays. It was showed good and similar activity than ascorbic acid and BHA by DPPH method: IC<sub>50</sub>= 220µg/mL for hydroethanol extract.*

### KEYWORDS:

*Populus nigra L. extracts, Antibacterial and antifungal activities, DPPH antioxidant power, Ferric reducing antioxidant power assay (FRAP).*

### 1. INTRODUCTION:

Medicinal plants are a very important natural resource whose valuation requires a perfect knowledge of the properties to develop. The medicinal activities of herbal depend on the presence of various bioactive agents belonging to different chemical classes (Ouraïni et al., 2005).

In many African and Asian countries, herbal medicine continues to be widely used. All these figures show that people are turning back to traditional medicine and medicinal plants mainly to (Muthu et al., 2006).

In Algeria, the empirical use of plants continues to maintain a high popularity [(Benmerabet and Abed, 1982) ; (Boulos, 1983)]. The Algerian people are sometimes preying of quackery ignorant and dangerous for patients. Many plants are known for their therapeutic properties, especially for their antiseptic, antibacterial and antioxidant effect, as Rosemary, Sage, Thyme, Garlic, Anise, Chamomile, Eucalyptus, Grenadier, mild Orange, etc ... (Ali-Delille, 2013).

For this, the use of medicinal plants with biological properties is one of the most interesting research areas to explore. Our work is based in this perspective is to determine the chemical composition of extracts of black poplar buds (*Populus nigra*) in the first time and secondly to highlight their antibacterial and antioxidant activities. This species is a member of Salicaceae family (family with 350 species), Greek "People", Latin for "to stir: tree leaves trembling. Flowering occurs in April and May. This tree, that can live up to 150 years, is very demanding in water and light, it is present in almost all of Europe and Northern Africa, especially the Northern Algerian, and more exactly, Elkala, Kabylie and Tlemcen [(Belouad, 200) ; (Ali-Delille, 2010)].

## 2. EXPERIMENTAL

Black poplar buds were collected in March - April 2010 from Dzarifet in Tlemcen, the West Northern of Algeria (GPS coordinates: 34° 53' 24" N 1° 19' 12" W). The plant was botanically identified by Mr. Yebedri (forestry engineer) and a voucher specimen of the plant was deposited in the Herbarium of the Laboratory of Botany, Department of Biology, Tlemcen University, Algeria. Before extraction, the buds can be dried away from the light.

### 2.1. Extracts

#### 2.1.1. Preparation of extracts

Ten grams of the pulverized materials were extracted by maceration with 100ml of solvent (hexane, chloroform, methanol and water) and subjected to continuous agitation at 200 rpm for 24 hours, at room temperature (25-28°C). The solution thus obtained is filtered, using filter paper (Whatman n° 4). The filtrate was evaporated in a rotary evaporator, until the extracts became completely dry and were totally dissolved in dimethylsulphoxide (DMSO) and stored in a labelled, sterile screw-capped bottle at +4°C until use.

#### 2.1.2. Chemical study

This study helps to show up the main chemical groups present in the plant in a qualitative way. The ground spice was tested for térpenoïdes, alkaloids and phenolic compounds (tannins, anthocyanes, flavonoids, coumarins, quinones). phytochemical study is performed according to the protocols of Dohou and al. (2003), Karumi and al. (2004) Oloyede (2005) and Edeoga (2005).

## 2.2. Antibacterial and antifungal activities

### 2.2.1. Microbial strains

Antimicrobial activities of *P. nigra* extracts were tested against 11 strains of bacteria: Gram-positive bacteria: *Staphylococcus aureus* (ATCC 25923), *Bacillus cereus* (ATCC 10876), *Enterococcus faecalis* (ATCC 49452), *Listeria monocytogenes* (ATCC 15313), Gram-negative bacteria: *Pseudomonas aeruginosa* (ATCC 27853), *Escherichia coli* (ATCC 25922), *Salmonella typhimurium* (ATCC 13311), *Acinetobacter baumannii* (ATCC 19606), *Citrobacter freundii* (ATCC 8090), *Proteus mirabilis* (ATCC 35659), *Klebsiella pneumoniae* (ATCC 700603) and 2 yeasts : *Candida albicans* (ATCC 26790), *Candida albicans* (ATCC 10231). Strains tested cultures are maintained in their proper slants at 4°C.

### 2.2.2. Screening for antibacterial and antifungal activities:

The disk diffusion method was used to determine antimicrobial activity of the *P. nigra* buds extracts (Espinel-Ingroff, 2007). Briefly, the recommended medium is sterile Mueller Hinton agar (MHA) supplemented with glucose and methylene blue for yeasts and MHA for bacteria strains. The Petri plates containing the MHA was incubated by swabbing with the microbial suspension ( $1 \times 10^6$  cells/mL), using sterile cotton-tipped swabs, and poured into Petri dishes to give a solid plate. Ten microliters of extracts dissolved in DMSO were applied on sterile paper discs (6 mm in diameter, Whatman n°1). The discs were deposited on the surface of incubated agar plates. Plates were kept for 15 minutes to enable prediffusion of the substances into the agar and then incubated at 35 °C and 37°C for 24 hours, for yeasts and bacteria respectively. The diameters of the inhibition zones were measured in millimeters. All the tests were performed in triplicate.

### 2.2.3. Micro-well determination (CMI)

Inocula of the microorganisms were prepared from 18 h. Cultures and the suspensions were adjusted to  $10^8$  CFU/mL of bacteria or  $10^6$  CFU/mL of yeasts with different concentrations of crude extracts (table 3). This test was repeated in triplicate. Gentamicin, ketoconazole and amphotericin B were used as reference antimicrobials. The antibacterial and antifungal activities of DMSO were tested for each microorganism (Sokmen et al. 2004).

## 2.3. Antioxidant activity

### 2.3.1. Quantification of total phenolic contents

Total phenolic contents of ethanolic extract were determined using Folin–Ciocalteu reagent using gallic acid as a standard (Li et al., 2008). 200 µL of the dilute extract solutions containing 40 µg of the hydroalcoholic were added to 1 mL of Folin–Ciocalteu reagent (diluted in distilled water). After 4 min, 800 µL of Na (75 mg/mL) solution was added and the mixture was allowed to stand for 45 min at room temperature. After incubation, the absorbance was measured at 760 nm with a spectrophotometer (Optizen POP spectrophotometer). The same procedure was also applied to the gallic acid solution and a standard curve was obtained. The concentrations of phenolic compounds expressed as mg gallic acid equivalent per g (mgGAE/g) of extract were calculated according to the standard gallic acid graph. All experiments were carried out in triplicate.

### 2.3.2. Determination of total flavonoids contents

Total flavonoid contents of the hydroalcoholic buds extract of *P. nigra* were determined using the Dowd method as adapted by Arvouet-Grand et al., (1994). One milliliter of 2% aluminium trichloride ( $AlCl_3$ ) in methanol was mixed with 200 µg of extract. After 10 min of incubation, absorption was measured at 430 nm against a blank sample (1 mL of methanol without  $AlCl_3$ ). The concentrations of flavonoid compounds expressed as mg of catechin equivalent per g (mg CE/g) of extract were calculated according to the standard catechin graph. All experiments were carried out in triplicate.

### 2.3.3. DPPH radical scavenging assay

The diluted hydroalcoholic solutions (5, 10, 25, 50, 75, 100, 250, 500, 750 and 1000 µg/mL) were prepared in ethanol. An ethanolic DPPH solution (24 µg/mL) was freshly prepared and 2 mL of this solution was added to 50 µL of hydroalcoholic solutions in ethanol at different concentrations. After 30 min of incubation, the absorbance was measured at 517 nm using a spectrophotometer (UV/VIS Spectrophotometer OPTIZEN POP). The blank of 2 mL of DPPH

solution with 50 $\mu$ L of ethanol was used. The reduction of DPPH solution absorbance indicates an increase in DPPH radical scavenging activity (% of inhibition), using following equation:

$$\% \text{ DPPH radical scavenging} = [(A_0 - A)/A_0] \times 100$$

$A_0$ : Absorbance of blank;

A: Absorbance of tested sample solution at 30 min.

The same procedure was followed for the positive control: ascorbic acid and tert-butyl-4-hydroxyanisole (BHA). The ethanol was used for baseline correction.

### 2.3.4. Ferric reducing antioxidant power assay (FRAP)

Various concentrations of hydroalcoholic (5, 10, 25, 50, 75, 100, 250, 500, 750 and 1000 $\mu$ g/mL) in distilled water were mixed with phosphate buffer (2.5ml, 0.2M, pH6.6) and 1% (w/v) of potassium ferricyanide water solution (2.5mL). The mixture was incubated at 50 $^{\circ}$ C for 20min. Aliquots of trichloroacetic acid (2.5mL, 10%, aqueous solution (w/v)) were added to the mixture which was then centrifuged at 3000 rpm for 10min. The supernatant (2.5mL) was mixed with distilled water (2.5ml) and a freshly prepared ferric chloride solution (0.5mL, 0.1% (w/v)). After 30min of incubation at room temperature in the dark, the absorbance of the resulting solution was measured at 700nm using a spectrophotometer (UV/VIS Spectrophotometer OPTIZEN POP) (Oyaizu, 1986). Ascorbic acid and BHA were used as positive control. The results were expressed graphically by plotting absorbance against concentration.

## 3. RESULTS

The phytochemical screening of the flower buds of *P. nigra* specie has shown the absence of quinones, anthocyanes and saponosids. However, these buds, among other sterol substances, flavonoids, tannins, terpenoids and alkaloids, these substances have been identified as antimicrobial and / or antioxidant products. The results of this study show that black poplar buds are a major source of polyphenols, alkaloids and terpenes compounds.

These secondary metabolites can be an excellent herbal alternative. Undeniable authors have shown that the salicaceae family contains various aromatic compounds such as caffeic acid, isofelurique, p-coumaric, salicin, salicylic acid, salicortin, the salicin alcohol, the salicyloylsalicine, aromatic ketones, free fatty acids, organic acids, 4-ethylphenol, terpenoids, catechol, the flavanone (eriodictyol, pinocembrin and pinostrobin), the isoflavones (chrysin, apigenin), flavonols (galangin, kaempferol, quercetin, rutin, quercetin 3-methyl ether) as majority compounds. In addition, more than 160 types of compounds have been isolated from species of the genus *Populus*, the majority are triterpene esters, sterols, flavonoids, alkaloids, lactones, lignans and resins [(Bankova et al., 1989); (Greenaway and Whatley, 1991); (Morreel et al., 2006); (Dudonné et al., 2011)]. The results of our phytochemical extracts of *P. nigra* buds study, going in the same direction.

A study was conducted by Isidorov and Vinogorova in 2003 on the chemical composition of the hexane and ether extract of *P. nigra* and *P. balsamifera* buds. The extracts were obtained by selective extractions and analyzed by GC / MS. The results exhibit the presence of volatile compounds, with 50 and 51 compounds for the hexane and ether extracts respectively. These various aromatic moieties are hydrocarbon sesquiterpenes, sesquiterpenoids, cinnamic acid, aromatic compounds (C<sub>6</sub>-C<sub>10</sub>), aliphatic acids, and phenolic carboxylic acids, flavonoids, ect  
....

Table 1 showed that extracts present a good antimicrobial activity (7 to 43mm) against tested strains. The maximum zone of inhibition were obtained with chloroform extract recorded *E. faecalis* (36 mm), and aqueous extracts against *C. albicans* ATCC 10231 (43mm). The *in vitro*

antibacterial and antifungal activities of *P. nigra* buds extracts were evaluated in the second time by the minimum inhibitory concentration (MIC) test against some pathogenic bacteria and yeasts (Table 2). The important MICs of extracts were observed against *C. albicans* ATCC 10231 (45.1µg/mL) and *E. faecalis* (74.2µg/mL), with aqueous and chloroform extracts respectively.

The antimicrobial activity of *P. nigra* extracts might be related to secondary metabolites present in buds. The Gram (+) bacteria were more sensitive to these extracts. This suggestion has been confirmed in previous studies. Smith-Palmer et al. (1998), Marino et al. (1999) and Inouye et al. (2001) have shown that Gram positive bacteria are generally more sensitive to plants extracts than Gram negative.

Chao et al. (2000) explained that Gram negative bacteria are equipped with peptidoglycan layer disposed between the plasma membrane and an external base consisting of lipopolysaccharides

and proteins. This structure can prevent the extracts penetration or protect the peptidoglycan layer against antimicrobial compounds. The lipopolysaccharides (LPS) of Gram negative bacteria provides a barrier to inhibit the permeability of hydrophobic substances like essential oils, which may come and prevent the growth of Gram positive bacteria (Chao et al., 2000).

During our literature search, we found that some studies were interested in evaluating biological activities of naturally propolis from several species of the genus *Populus*. The study of Jug et al (2014) performed on the evaluation of the antimicrobial activity of extracts from several samples of propolis obtained from *Populus*, has shown that alcoholic and aqueous extracts were strongly inhibited growth of *S. mutans*, *B. ceureus*, *P. aeruginosa* and *C. albicans*. The results we have obtained are relatively in the same direction.

The amounts of total phenolics and flavonoids from hydroethanolic extract were determined spectrometrically according to the Folin–Ciocalteu and the method with aluminum chloride (AlCl<sub>3</sub>) respectively. The extract of *P. nigra* buds presents high polyphenol (674.66 mg GAE/g) and flavonoids (162.5 mg CE/g) contents.

Antioxidant properties of hydroalcoholic extract were evaluated to find a new natural source of antioxidant. The results obtained at different concentrations (5, 10, 25, 50, 75, 100, 250, 500, 750 and 1000µg/mL) are shown in Figure1 and Figure2.

Figure1. DPPH radical-scavenging of hydroethanolic extract from *P. nigra*

Figure 2. Ferric reducing antioxidant power assay (FRAP) of hydroethanolic extract from *P. nigra* at different concentrations.

The best percentages of antioxidant activities were observed for the synthetic antioxidants AA, hydroethanolic extract from *P. buds* BHA and (96.56, 93.62 and 90.53%, respectively), at a *nigra* concentration of 1mg/mL.

The antioxidant capacity of hydroethanolic extract was determined by calculating the IC<sub>50</sub> (Table 3). It presents the extract concentration required to reduce 50% of DPPH radical. It is inversely proportional to the percentage of scavenging free radical DPPH.

Table 3. Antioxidative activity expressed as IC<sub>50</sub> values for DPPH scavenging activity of hydroethanolic extract of *P. nigra* buds.

	IC <sub>50</sub> (µg/m)		
	EtOH/Water	BHA	AA
<i>P. nigra</i>	220	230	210

The IC<sub>50</sub> results show that hydroalcoholic extract of *P. nigra* have a strong reducing effect on the radical DPPH (IC<sub>50</sub>=220µg/mL). This value is comparable to those of the BHA (230µg/mL) and ascorbic acid (210µg/mL).

The results of the antioxidant activity by the FRAP method show that the hydroalcoholic extract of *P. nigra* has the ability to reduce the iron. To a final concentration of 1mg/mL, an optical density of 0.7235 was measured for this extract. This activity remains relatively lower than that obtained with AA and the BHA which have optical density of 2.2476 and 2.1361 respectively at the same concentration.

The Evaluation of antioxidant activity of *P. nigra* buds showed that hydroalcoholic extract exerts a trapping of the free radical DPPH power comparable to that obtained with the reference antioxidants (BHA and ascorbic acid). In addition, the colorimetric analysis revealed high levels of phenolic compounds in hydroalcoholic extract of this species. This activity depends on the chemical composition of this extract.

These results contradict those found by Dudonné and al (2011). These authors have conducted a study on the phenolic composition of the black poplar buds aqueous extract and its antioxidant activity by Oxygen Radical Absorbance Capacity method (ORAC). The results have showed that the aqueous extract contains an important phenolic content and has a moderate antioxidant activity. The main identified phenolic compounds are the phenolic acid and flavonoid aglycones (Dudonné et al., 2011).

Another study carried out on the rates of polyphenols and the evaluation of antioxidant activity of propolis extracts from black poplar. The results thus obtained have showed that propolis contain variable contents of polyphenols and flavonoids with maximum 353,9mg / g and 123,3mg / g respectively (Jug, et al., 2014). In addition, these same samples exert remarkable antioxidant activities by the three methods tested (FRAP, DPPH and Beta carotène- linoleic acid). IC<sub>50</sub> obtained from DPPH method were ranging from 29 to 114,4µg / mL, depending on samples of propolis.

The study of Debbache et al.(2014) on the evaluation of the anti-inflammatory, antimicrobial and determining the rate of phenolic compounds from black poplar buds from Eastern region of Algeria, has shown that that extract obtained after two successive extractions with water and chloroform, has good trapping ability of the free radical DPPH with an IC<sub>50</sub> of 187,90µg/mL.

#### 4. CONCLUSION

The results suggest that extracts from the buds of *P. nigra* of Algeria could be a source of secondary metabolites, especially polyphenol and volatile compounds which present an important health promoting compound. Our studies have showed that hydroethanolic extract of black poplar buds exerts good antioxidant activity similar than BHA and ascorbic acid activity.

Our results also indicated that aqueous extract has a good antifungal activity *in vitro*. These results could support the use of this specie by traditional healers to treat several diseases.
